

What is a Software Product?

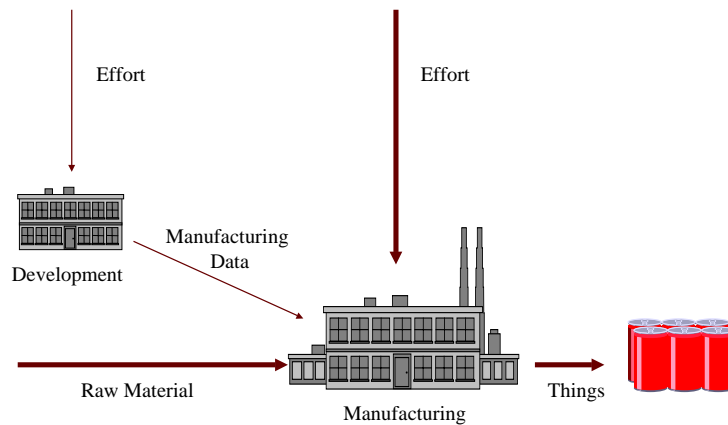

The Organisation of Things, Files and People

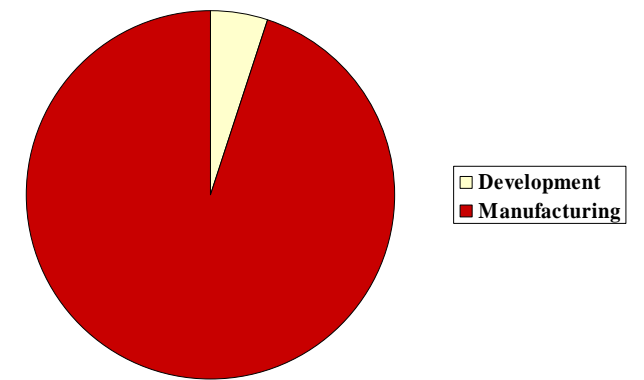

Manufacturing: Production of Things

Traditional Production

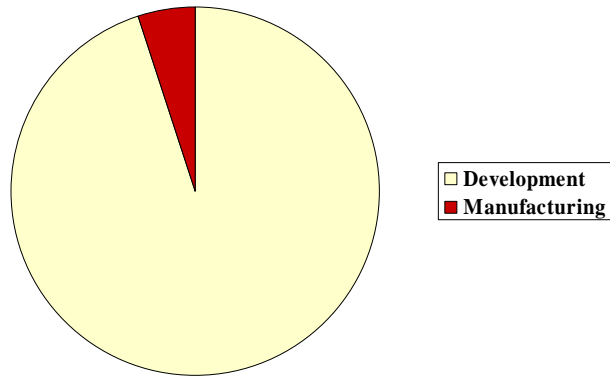

Traditional Production

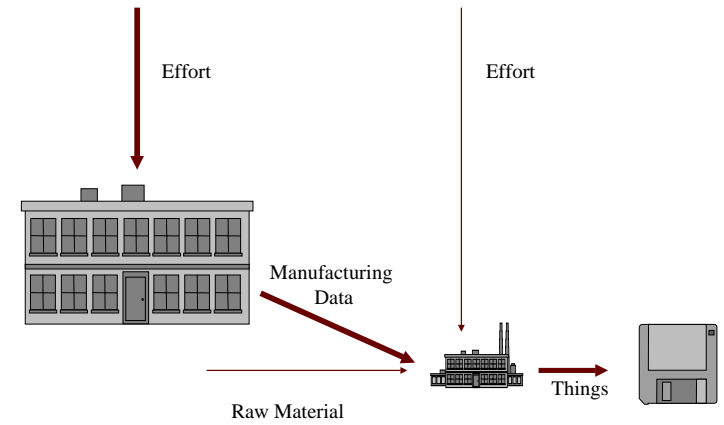

Production of Software

Production of Software

The Reusable Development Product

Types of Reuse

- ◆ Reuse within parts of a delivered product
- ◆ Reuse between releases of a delivered product
- ◆ Copy&Paste Reuse
- ◆ Reuse between different releases of different delivered products

Non-traceable Reuse (~Pfleeger:Compositional Reuse)

- ◆ Use need not to be documented
- ◆ Generic existing components
- ◆ Platform functionality
- ◆ Changes must be backward compatible
- ◆ Supplier and user may be in different organizations
- ◆ Quality is extremely important

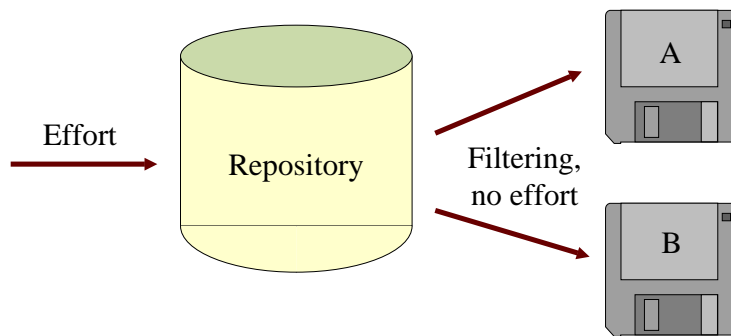

Traceable Reuse (~Pfleeger:Generative Reuse)

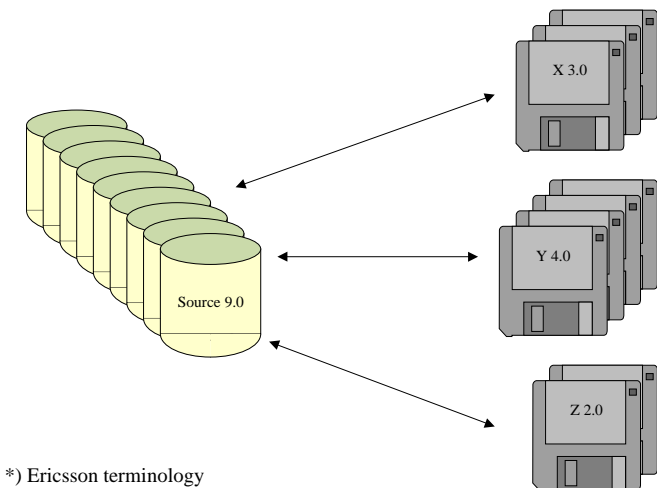

- ◆ Explicit and documented use
- ◆ Components useful only in a certain context
- ◆ Application functionality
- ◆ All using functionality may be updated to allow non-backward compatible changes
- ◆ Supplier and user must be in the same organization
- ◆ Normal quality requirements

Production for Reuse

Source Systems* and Delivery Systems*

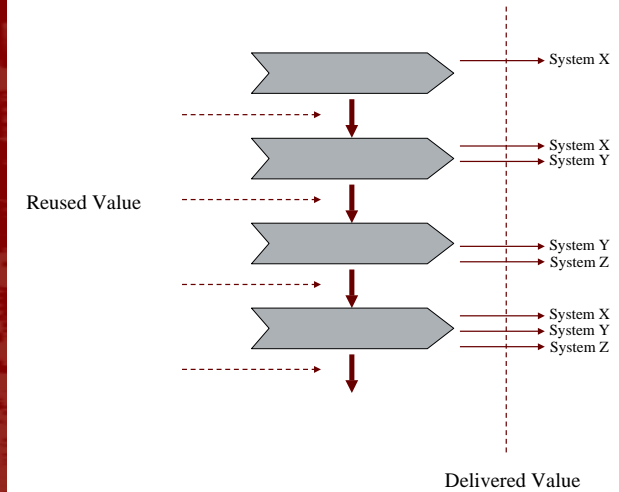

*) Ericsson terminology

Life Cycle

Evolving the Source System

Value = Volume * Quality

- ◆ Delivered Quality
 - As perceived by the customer
- ◆ Reused Quality
 - As perceived by the future developer
- ◆ Maintained Quality
 - As perceived by maintenance responsible

Reuse:

*The Art of Organizing
Produced Information*

Storing Produced Information:

Data bases

Files and documents

Peoples minds

Organizing People:

Misplacing people means deterioration of Reused Value

Simple Folder-Type Hierarchy

Versioning and Filtering

Product Tracking

Fault Tracking

- ◆ Which Source Systems contain the fault?
- ◆ Which Delivery System releases are produced from the faulty Source system?
- ◆ Which Delivery Systems include the faulty functionality

Feature Tracking

- ◆ In which release of a system will a certain feature be available?
- ◆ Which functionality has been delivered to a certain customer?
- ◆ Have all promised functionality been delivered?
- ◆ Which versions of different products are compatible?
- ◆ ...

Time To Market (TTM)

The time from when a product is wanted by the market until it is available for purchase.

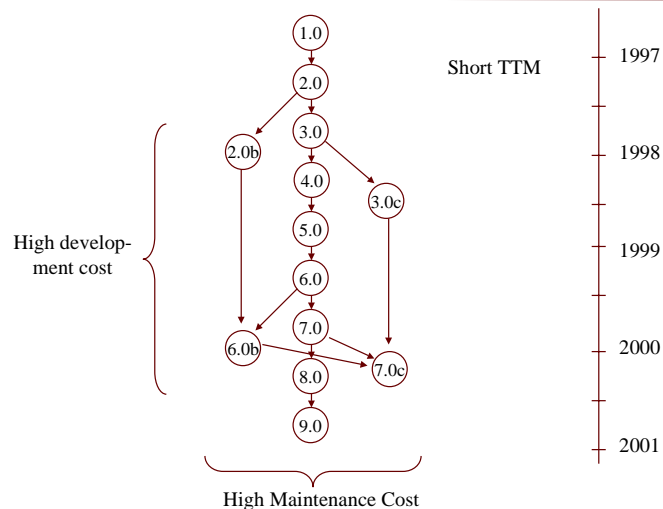

Sequential Development

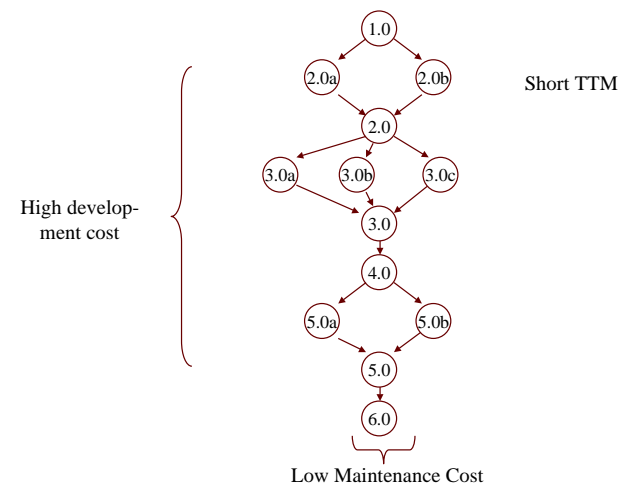

Low Development Cost
Low Maintenance cost
High TTM

Non Sequential development

Parallel Development

TTM Approaches: Examples

- ◆ Micro Project
- ◆ Branch/Merge
- ◆ Distributed Feature/Centralized Structure

Note: These are still unproven techniques

Orthogonal views

Structure View:

- Subsystems
- Classes
- Source Files
- Processes

Feature View:

- Abilities
- Functionality
- Use Cases

The Micro Project Approach

- ◆ Each development cycle is a very short, but complete project.
- ◆ Sequential development
- ◆ Few features developed in each cycle.
- ◆ Lead time < 3 months.
- ◆ Feature roll out planning for each cycle.
- ◆ Overlapping development => Product release every 4 weeks possible.
- ◆ People keep their roles between projects.
- ◆ Significant architectural impacts not possible.
- ◆ Works only for mature products.

The Branching/Merging Approach

- ◆ Parallel projects make uncoordinated impacts to different “branches” of a part of the product.
- ◆ Projects are feature oriented.
- ◆ After development is finished, branches are “merged” with support from tools.
- ◆ Merging is a separate design activity that may be more costly than feature development.
- ◆ Requires that features don’t have strong structural overlap.
- ◆ More suitable for administrative than real-time applications.
- ◆ Significant architectural impact not possible.

Distributed Feature/ Centralized Structure Approach

- ◆ Parallel feature oriented projects work independently in separate functional areas.
- ◆ Feature oriented projects assign all structural impacts to a common structure oriented project.
- ◆ Structure oriented project coordinates architecture and approves all impacts.
- ◆ People in structure oriented project keeps their roles between projects.
